

EYES ON YOU

Amazing Animal Eyes

Chameleons have eyes that move independently. This means that one eye can be looking at one thing and the other eye can be looking at another thing at the same time!

Most insects have compound eyes. Though they are different from the eyes discussed in the experiment, they do the same thing by allowing insects to see in almost every direction around them.

EYES ON YOU

Falcons have very large and powerful eyes that let them spot prey easily and from great distances. Some falcons are even able to spot prey up to 17 soccer fields away!

Like falcons, owls also have very large eyes that let them see well. However, owl eyes have a special adaptation that lets them see at night. Their night vision is so good that most owls hunt at nighttime in complete darkness!
